

A five operations, each changing what the number means

$$\tilde{S}_d(x) = \gamma_d(x) \cdot \max_{(t, w) \in G(d)} w \cdot \max(0, E_t(\hat{q}_t(x)))$$

B probability against base rate

tick = endpoint base rate, dot = this compound

C one condition's targets

tick at zero = engaged signal is exactly zero

D what is reported

orange line = the 0.30 reporting threshold

Worked on donepezil. It is a training compound of the AChE endpoint at a maximum Tanimoto of 1.000, so its AChE probability is recall rather than prediction. This figure explains what the pipeline computes; how well it computes it on novel chemistry is Figure 11.
