

A what a censored measurement can settle

a bound settles the label whenever the whole interval falls on one side of the cut

B class balance, before and after

C and what it did to the models

Classification gets slightly harder and regression gets better, both in the expected direction: replacing decoys with compounds that were assayed and did not bind removes an easy negative class from the classifiers, and adds real low-potency anchors to the regressions. BBB are flat at exactly zero, not missing: neither draws from a ChEMBL target, so no negatives were recovered for them.
